

I am working in banking domain. can you give few use cases in banking sector using agent bricks(preferable with multi agent) which are still open or latest ask in real world

The banking sector is rapidly moving away from simple chatbots toward compound AI systems. Databricks **Agent Bricks**—their enterprise framework for building and governing AI agents—is seeing massive adoption in financial services because it solves the hardest part of generative AI in highly regulated industries: **context, governance, and deterministic execution**.

Instead of relying on a single Large Language Model (LLM) to guess an answer, banks are using a **Multi-Agent Supervisor** pattern. The supervisor receives a complex request, breaks it into subtasks, routes them to specialized agents (like a SQL agent for data, or a compliance agent for rule checks), and synthesizes a fully cited response.

Here are the most prominent, real-world multi-agent use cases currently being built and deployed in banking using Agent Bricks:

1. AI-Powered Wealth Management & Investment Advisory

The Ask: Wealth advisors need to instantly synthesize market data, client portfolios, and complex regulatory rules to provide personalized advice, but manual research takes hours.

The Multi-Agent Architecture:

Supervisor Agent: Takes the advisor's natural language request (e.g., "Is Client X suitable for this tech ETF?") and decomposes the workflow.

Quantitative Agent (Genie Space): Queries structured, governed data in Unity Catalog to compute real-time KPIs like portfolio exposure, ROI, and P/E ratios.

Qualitative/Sentiment Agent: Analyzes unstructured data like recent earnings calls, SEC filings, and financial news to extract risk signals.

Compliance Agent: Cross-references the proposed investment against regulatory rules, KYC (Know Your Customer) profiles, and the client's documented risk tolerance.

The Impact: The supervisor synthesizes the findings into a single, fully cited recommendation. This reduces thesis-generation time from hours to minutes, reduces post-trade adjustments, and guarantees compliance-by-design.

2. Intelligent Loan Underwriting & Corporate Onboarding

The Ask: Commercial lending and corporate onboarding require analysts to parse hundreds of pages of unstructured documents (tax returns, insurance policies, legal filings) and cross-reference them with core banking systems.

The Multi-Agent Architecture:

Document Intelligence Agent: Uses RAG (Retrieval-Augmented Generation) backed by Databricks Vector Search to parse and extract clauses, liabilities, and terms from unstructured PDFs.

Credit/Risk Scoring Agent: Connects to transactional databases to run deterministic risk-scoring algorithms and eligibility checks.

Policy Agent: Evaluates the combined structured and unstructured data against the bank's internal credit underwriting policies.

The Impact: Automates the manual "stare and compare" work, allowing human underwriters to focus purely on complex decision-making and significantly accelerating time-to-decision for commercial loans.

3. Automated AML Monitoring & Continuous KYC

The Ask: Traditional Anti-Money Laundering (AML) systems rely on rigid rules that generate massive amounts of false positives, while manual KYC reviews are too slow to keep up with real-time global risk.

The Multi-Agent Architecture:

Monitoring Agent: Continuously scans global public information, watchlists, and news across multiple markets to detect high-risk individuals or organizations.

Graph/Transaction Agent: Analyzes complex transaction webs and historical account behavior to flag suspicious fund routing.

Audit & Reporting Agent: Automatically drafts the Suspicious Activity Report (SAR) with a clear chain-of-thought and data lineage, proving exactly why a transaction was flagged.

The Impact: Banks are seeing massive reductions in manual exceptions and legacy operational costs, with highly traceable rule checks per decision to quickly satisfy regulators.

4. Hyper-Personalized "Appless" Retail Banking

The Ask: Retail banks want to move beyond generic marketing and offer proactive, personalized financial actions directly in the channels customers use daily (like WhatsApp or SMS).

The Multi-Agent Architecture:

Customer Context Agent: Pulls real-time transaction history, spending habits, and life events from a Customer Data Platform (CDP).

Next-Best-Action Agent: Evaluates the context to recommend the most valuable action (e.g., "You have excess cash in checking, move it to high-yield savings" or offering a micro-loan at the point of sale).

Execution Agent: Securely triggers the action via APIs once the customer approves.

The Impact: This architecture powers billions of real-time recommendations annually, vastly improving conversion rates by removing the friction of navigating a traditional banking app.

Why Agent Bricks for these?

The differentiating factor for these use cases isn't just the LLMs—it's **Unity Catalog governance**. Agent Bricks natively inherits user identity and data permissions. If a junior analyst asks a multi-agent system for a client's risk profile, the agents can only retrieve and reason over the exact data that the junior analyst is authorized to see.

To see how financial organizations are actively putting these exact workflows into production, take a look at [AI Agents for Financial Services](#).
